Project Overview

This project demonstrates the development and deployment of a serverless cloud based web application using Amazon Web Services (AWS). The application allows users to submit and view questions stored in Amazon DynamoDB using AWS Lambda functions and API Gateway to process requests. The static frontend is hosted on Amazon S3, distributed through CloudFront, and monitored via CloudWatch.

The purpose of this project was to apply full stack development concepts using serverless architecture principles to create a scalable, cost efficient, and secure application.

Technologies and Services Used

- AWS S3 – Static website hosting for the frontend
- AWS Lambda – Serverless compute for backend logic
- Amazon API Gateway – RESTful API interface between frontend and backend
- Amazon DynamoDB – NoSQL database for storing questions
- Amazon CloudFront – CDN for caching and HTTPS delivery
- Amazon CloudWatch – Logging and performance monitoring
- AWS IAM – Role-based access control for security and least privilege
